

Integer and float (Numeric):

Python supports two types of numbers - integers and floating point numbers.

- Integers

Integers are whole numbers, such as 5, 22, 3000, 100531, and so on.

For example, the statement **y = 15** will store the value **15** in the variable **y**.

- Float

Float variables will have a numeric value with a decimal portion.

For example, the statement **z = 2.5** will store the floating-point value **2.5** in the variable **z**

Examples:

1. Age = 52
2. Weight = 62.53
3. Hours : 49
4. Height= 182.9
